Motivations

Quantitative Models of language structures

Linguistic structures exhibit syntagmatic information that is crucial for machine learning in Web Mining. The common grammatical modeling framework is the one of (phrase structure) grammars, that can produce often ambiguous readings:

S -> NP V
 S -> NP
 NP -> PN
 NP -> N
 NP -> Adj N
 N -> "imposta"
 Adj -> "pesante"
 PN -> "Pesante"

Exercises 0

Motivations

The role of Quantitative Approaches

Weighted grammars are models of (possibly limited) *degrees of grammaticality*. They are meant to deal with a large range of ambiguity problems:

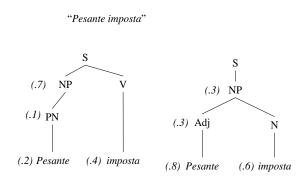

<pre>3. NP -> PN 4. NP -> N 5. NP -> Adj N 6. N -> imposta 7. V -> imposta 8. Adj -> Pesante .</pre>	1.	S	->	NP V	.7
<pre>4. NP -> N . 5. NP -> Adj N . 6. N -> imposta . 7. V -> imposta . 8. Adj -> Pesante .</pre>	2.	S	->	NP	.3
5. NP -> Adj N 6. N -> imposta 7. V -> imposta 8. Adj -> Pesante	3.	NP	->	PN	.1
6. N -> imposta . 7. V -> imposta . 8. Adj -> Pesante .	4.	NP	->	Ν	.6
<pre>7. V -> imposta . 8. Adj -> Pesante .</pre>	5.	NP	->	Adj N	.3
8. Adj -> Pesante .	6.	Ν	->	imposta	.6
2	7.	V	->	imposta	.4
9. PN -> Pesante .	8.	Adj	->	Pesante	.8
	9.	PN	->	Pesante	.2

$$P(X_k = p_4 | X_{k-1} = p_1) = 0 \quad \forall k$$

Hidden Markov Models

A Simple Example of Hidden Markov Model

Crazy Coffee Machine

- Two states: Tea Preferring (*TP*), Coffee Preferring (*CP*)
- Switch from one state to another randomly
- Simple (or visible) Markov model: Iff the machine output *Tea* in *TP* AND *Coffee* in *CP*

What we need is a description of the random event of switching from one state to another. More formally we need for each time step n and couple of states p_i and p_j to determine following conditional probabilities:

$$P(X_{n+1}=p_j|X_n=p_i)$$

where p_t is one of the two states *TP*, *CP*.

HMM and POS tagging References Exercises

Hidden Markov Models

A Simple Example of Hidden Markov Model

Crazy Coffee Machine

Assume, for example, the following state transition model:

	TP	СР
TP	0.70	0.30
СР	0.50	0.50

and let *CP* be the starting state (i.e. $\pi_{CP} = 1$, $\pi_{TP} = 0$).

Potential Use:

- What is the probability at time step 3 to be in state *TP*?
- What is the probability at time step *n* to be in state *TP*?
- What is the probability of the following sequence in output: (*Coffee*, *Tea*, *Coffee*)?

Hidden Markov Models

A Simple Example of Hidden Markov Model (2)

Solution for the problem 1 For the given state sequence X = (CP, TP, TP) $P(O_1 = Cap, O_2 = Cof, X_1 = CP, X_2 = TP, X_3 = TP) =$ $P(O_1 = Cap, O_2 = Cof | X_1 = CP, X_2 = TP, X_3 = TP)P(X_1 = CP, X_2 =$ $TP, X_3 = TP)) =$ P(Cap, Cof | CP, TP, TP)P(CP, TP, TP)) Now: P(Cap, Cof | CP, TP, TP) is the probability of output *Cap*, *Cof during* transitions from *CP* to *TP* and *TP* to *TP* and P(CP, TP, TP) is the probability of the transition chain. Therefore,

Hidden Markov Models

A Simple Example of Hidden Markov Model (2)

Solution for the problem 1 For the given state sequence X = (CP, TP, TP) $P(O_1 = Cap, O_2 = Cof, X_1 = CP, X_2 = TP, X_3 = TP) =$ $P(O_1 = Cap, O_2 = Cof | X_1 = CP, X_2 = TP, X_3 = TP)P(X_1 = CP, X_2 =$ $TP, X_3 = TP)) =$ P(Cap, Cof | CP, TP, TP)P(CP, TP, TP)) Now: P(Cap, Cof | CP, TP, TP) is the probability of output *Cap*, *Cof during* transitions from *CP* to *TP* and *TP* to *TP* and P(CP, TP, TP) is the probability of the transition chain. Therefore,

- = P(Cap|CP,TP)P(Cof|TP,TP) = (in our simplified model)
- $= P(Cap|CP)P(Cof|TP) = 0.2 \cdot 0.2 = 0.04$

Advantages

Modeling linguistic tasks as Stochastic Processes

Advantages

There are several advantages to model a linguistic problem as an HMM

- It is a powerful mathematical framework for modeling
- It provides clear problems settings for different applications: estimation, decoding and model induction
- HMM-based models provides sound solutions for the above applications

We will see an example as the HMM modeling of POS tagging

HMM and POS tagging References

Exercises O

Advantages

Fundamental problems for HMM

Fundamental Questions for HMM

The complexity of training and decoding can be limited by the use of optimization techniques

- Given the observation sequence O = O₁,...,O_n and a model λ = (E,T,π), how to efficiently compute P(O|λ)? (*Language Modeling*)
- Given the observation sequence O = O₁,..., O_n and a model λ = (E,T,π), how do we choose the optimal state sequence Q = q₁,...,q_n responsible of generating O ? (*Tagging/Decoding*)
- How to adjust model parameters λ = (E, T, π) so to maximize P(O|λ)? (Model Induction)

HMM and POS tagging References

Exercises O

Advantages

HMM: Mathematical Methods

All the above problems can be approached by several optimization techniques able to limit the complexity.

- Language Modeling via *dynamic programming* (Forward algorithms) (O(n))
- Tagging/Decoding via *dynamic programming* (O(n)) (Viterbi)
- Parameter estimation via *entropy minimization* (the *EM* algorithm)

A relevant issue is the availability of source data: supervised training cannot be applied always

HMM and POS tagging References

Exercises 0

HMM and POS tagging

The HMM Model of POS tagging:

- HMM States are mapped into POS tags (t_i) , so that $P(t_1,...,t_n) = P(t_1)P(t_2|t_1)...P(t_n|t_{n-1})$
- HMM Output symbols are words, so that $P(w_1,...,w_n|t_1,...,t_n) = \prod_{i=1}^n P(w_i|t_i)$
- Transitions represent moves from one word to another Note that *the Markov assumption is used*
 - to model probability of a tag in position *i* (i.e. *t_i*) only by means of the preceding part-of-speech (i.e. *t_i*-1)
 - to model probabilities of words (i.e. w_i) based only on the tag (t_i) appearing in that position (i).

HMM and POS tagging

nces Exercises O

▲□▶▲□▶▲□▶▲□▶ ▲□ ● のへで

HMM and POS tagging

The final equation is thus:

$$(t_1,...,t_n) = argmax_{t_1,...,t_n} P(t_1,...,t_n | w_1,...,w_n) = argmax_{t_1,...,t_n} \prod_{i=1}^n P(w_i | t_i) P(t_i | t_{i-1})$$

Fundamental Questions for HMM in POS tagging

- Given a model what is the probability of an output sequence, O: *Computing Likelihood, Language Modeling.*
- Given a model and an observable output sequence O (i.e. words), how to determine the sequence of states $T = (t_1, ..., t_n)$ such that it is the best explanation of the observation O:

Decoding Problem

Given a sample of the output sequences and a space of possible models how to find out the best model, that is the model that best explains the data: *how to estimate parameters?*

Fundamental Questions for HMM in POS tagging

- 1. (Language Modeling) Not much relevant for POS tagging, where $(w_1, ..., w_n)$ are always known. Trellis and dynamic programming technique.
- 2. (Decoding) Viterbi Algorithm for evaluating *P*(*T*|*O*). Linear in the sequence length.
- 3. Baum-Welch (or Forward-Backward algorithm), that is a special case of Expectation Maximization estimation. Weakly supervised or even unsupervised. *Problems*: Local minima can be reached when initial data are poor.

HMM and POS tagging References

HMM and POS tagging References

ces Exercises

Exercise

Consider a two-bit register. The register has four possible states: 00, 01, 10 and 11. Initially, at time 0, the contents of the register is chosen at random to be one of these four states, each with equal probability. At each time step, beginning at time 1, the register is randomly manipulated as follows: with probability 1/2, the register is left unchanged; with probability 1/4, the two bits of the register are exchanged (e.g., 01 becomes 10); and with probability 1/4, the right bit is flipped (e.g., 01 becomes 00). After the register has been manipulated in this fashion, the left bit is observed. Suppose that on the first three time steps, we observe 0, 0, 1.

- Formulate the register as an HMM. What is the probability of transitioning from every state to every other state? What is the probability of observing output (0 or 1) in each state?
- What is the probability of being in each state at time *t* after observing only the first *t* bits, for *t* = 1,2,3.
