

AUTOMATIC CLASSIFICATION: NAÏVE BAYES

WM&R 2020/21 – 2 UNITS

R. Basili

(many slides borrowed by: H. Schutze)

Università di Roma “Tor Vergata”

Email: basili@info.uniroma2.it

Summary

- The nature of probabilistic modeling
- Probabilistic Algorithms for Automatic Classification (AC)
 - Naive Bayes classification
 - Two models:
 - Univariate Binomial (FIRST UNIT)
 - Multinomial (Class Conditional Unigram Language Model) (SECOND UNIT)
- Parameter estimation & Feature Selection

Motivation: *is this spam?*

From: "" <takworld@hotmail.com>

Subject: real estate is the only way... gem oalvgkay

Anyone can buy real estate with no money down

Stop paying rent TODAY !

There is no need to spend hundreds or even thousands for similar courses

I am 22 years old and I have already purchased 6 properties using the methods outlined in this truly INCREDIBLE ebook.

Change your life NOW !

=====

Categorization/Classification

- Given:
 - A description of an instance, $x \in X$, where X is the *instance language* or *instance space*.
 - Issue: how to represent text documents.
 - A fixed set of categories:
 $C = \{c_1, c_2, \dots, c_n\}$
- Determine:
 - The category of x : $c(x) \in C$ (or 2^C), where $c(x)$ is a *categorization function* whose domain is X that correspond to the classe(s) of C suitable for x .
- Learning problem:
 - We want to know how to build the categorization function c (“classifier”).

Document Classification

(Note: in real life there is often a hierarchy; and you may get papers on ML approaches to Garb. Coll., i.e. c is a multiclassification function)

Text Categorization tasks: examples

- Labels are most often *topics* such as Yahoo-categories
 - e.g., "finance" "sports" "news>world>asia>business"
- Labels may be *genres*
 - e.g., "editorials" "movie-reviews" "news"
- Labels may be *opinion* (as in Sentiment Analysis)
 - e.g., "like", "hate", "neutral"
- Labels may be *domain-specific binary*
 - e.g., "interesting-to-me" : "not-interesting-to-me",
"spam" : "not-spam",
"contains adult language" : "doesn't",
"is a fake" : "it isn't"

Text Classification approaches

- *Manual classification*
 - Used by Yahoo!, Looksmart, about.com, ODP, Medline
 - Very accurate when job is done by experts
 - Consistent when the problem size and team is small
 - Difficult and expensive to scale
- Usually, basic rules are adopted by the editors wrt:
 - Lexical items (i.e. words or proper nouns)
 - Metadata (e.g. original writing time of the document, author,)
 - Sources (e.g. the originating organization, e.g. a sector specific newspaper, or a social network)
 - *Integration of different criteria*

Automatic Classification Methods

- Automatic document classification better scales with the text volumes (e.g. user generated contents in social media)
- *Hand-coded rule-based systems*
 - One technique used by CS dept's spam filter, Reuters, CIA, Verity, ...
 - e.g., assign category if document contains a given boolean combination of words
 - Standing queries: Commercial systems have complex query languages (everything in IR query languages + accumulators)
 - Accuracy is often very high if a rule has been carefully refined over time by a subject expert
 - Building and maintaining these rule bases is expensive

Classification Methods (2)

- *Supervised learning of a document-label assignment function*
 - Many systems partly rely on machine learning
(Autonomy, MSN, Yahoo!, Cortana),
 - Algorithmic variants can be:
 - **k-Nearest Neighbors** (simple, powerful)
 - **Rocchio** (geometry based, simple, effective)
 - **Naive Bayes** (simple, common method)
 - ...
 - **Support-vector machines** and **neural networks** (very accurate)
 - No free lunch: requires **hand-classified training data**
 - Data can be also built up (and refined) by amateurs (crowdsourcing)
- **Note:** many commercial systems use a mixture of methods!

Bayesian Methods

- Learning and classification methods based on **probability theory**.
 - **Bayes theorem** plays a critical role in probabilistic learning and classification.
- STEPS:
 - Build a **generative model** that approximates **how data are produced**
 - Use **prior probability** of each category when no information about an item is available.
 - Produce, during categorization, the **posterior probability distribution over the possible categories** given a description of an item

Bayes' Rule

- Given an instance X and a category C the probability $P(C, X)$ can be used as a joint event:

$$P(C, X) = P(C | X)P(X) = P(X | C)P(C)$$

- The following rule thus holds for every X and C :

$$P(C | X) = \frac{P(X | C)P(C)}{P(X)}$$

- What does $P(X|C)$ means?

Maximum a posteriori Hypothesis

$$h_{MAP} \equiv \operatorname{argmax}_{h \in H} P(h | X)$$

$$= \operatorname{argmax}_{h \in H} \frac{P(X | h)P(h)}{P(X)} =$$

As $P(X)$ is
constant

$$= \operatorname{argmax}_{h \in H} P(X | h)P(h)$$

Maximum likelihood Hypothesis

If all hypotheses are a priori equally likely, we only need to consider the $P(D/h)$ term:

$$h_{ML} \equiv \operatorname{argmax}_{h \in H} P(X | h)$$

Naive Bayes Classifiers

Task: Classify a new instance document D based on a tuple of attribute values $D=(x_1, x_2, \dots, x_n)$ into one of the classes $c_j \in C$

$$\begin{aligned}
 c_{MAP} &= \operatorname{argmax}_{c_j \in C} P(C_j | x_1, x_2, \dots, x_n) = \\
 &= \operatorname{argmax}_{c_j \in C} \frac{P(x_1, x_2, \dots, x_n | c_j) P(c_j)}{P(x_1, x_2, \dots, x_n)} = \\
 &= \operatorname{argmax}_{c_j \in C} P(x_1, x_2, \dots, x_n | c_j) P(c_j)
 \end{aligned}$$

Problems to be solved to apply Bayes

- Determine the notion of document as the joint event

$$D=(x_1, x_2, \dots, x_n)=(x^D_1, x^D_2, \dots, x^D_n)$$

- Determine how x_i is related to the document content
- Determine how to estimate
 - $P(C_j)$ for the different classes $j=1, \dots, k$
 - $P(x^D_i)$ for the different properties/features $i=1, \dots, n$
 - $P(x^D_1, x^D_2, \dots, x^D_n | C_j)$ for the different tuples and classes

- Define the law that select among the different

$$P(C_j | x^D_1, x^D_2, \dots, x^D_n) \quad j=1, \dots, k$$

- Argmax? Best m scores? Thresholds?

Problems to be solved to apply Bayes

- ➔ • Determine the notion of document as the joint event

$$D=(x_1, x_2, \dots, x_n)=(x^D_1, x^D_2, \dots, x^D_n)$$

- ➔ • Determine how x_i is related to the document content
- Determine how to estimate
 - $P(C_j)$ for the different classes $j=1, \dots, k$
 - $P(x^D_i)$ for the different properties/features $i=1, \dots, n$
 - $P(x^D_1, x^D_2, \dots, x^D_n | C_j)$ for the different tuples and classes

- Define the law that select among the different

$$P(C_j | x^D_1, x^D_2, \dots, x^D_n) \quad j=1, \dots, k$$

- Argmax? Best m scores? Thresholds?

Problems to be solved to apply Bayes

- Determine the notion of document as the joint event

$$D=(x_1, x_2, \dots, x_n)=(x^D_1, x^D_2, \dots, x^D_n)$$

- Determine how x_i is related to the document content

- IDEA: use words and their direct occurrences, as «signals» for the content

- Words are individual outcomes of the test of picking randomly one token from the text
- Random variables X can be used such that x_i represent $X=word_i$
- Multiple Occurrences of words in texts trigger several successful tests for the same word $word_i$; they augment the probability

$$P(x_i)=P(X=word_i)$$

Modeling the document content

- Variables X provide a description of a document D as they correspond to the outcome of a test
- D corresponds to the joint event of *one unique picking* of words $word_i$ from the vocabulary V , whose outcomes are
 - **Present** if $word_i$ occurs in D
 - **Not present** if $word_i$ does not occur in D
- It is a *binary event*, like a picking a **white** or **black** ball from a urn
- The joint event is the «parallel» picking of the ball for every (urn, i.e.) $word_i$ in the dictionary, that is *one urn per word* is accessed

- Notice how n (i.e. the number of features) here becomes the size $|V|$ of the vocabulary V
- Each feature x_i models the presence or absence of $word_i$ in D , and can be written as $X_i=0$ or $X_i=1$

This is the basis for the so-called Multivariate binomial model!

Problems to be solved to apply Bayes

- Determine the notion of document as the joint event
 $D=(x_1, x_2, \dots, x_n)=(x_{D1}, x_{D2}, \dots, x_{Dn})$

- Determine how x_i is related to the document content

- ➔ • Determine how to estimate

- $P(C_j)$ for the different classes $j=1, \dots, k$
- $P(x^D_i)$ for the different properties/features $i=1, \dots, n$
- $P(x^D_1, x^D_2, \dots, x^D_n | C_j)$ for the different tuples and classes

- Define the law that select among the different

$$P(C_j | x^D_1, x^D_2, \dots, x^D_n) \quad j=1, \dots, k$$

- Argmax? Best m scores? Thresholds?

Naïve Bayes Classifier: Naïve Bayes Assumption

- $P(c_j)$
 - Can be estimated from the frequency of classes in the training examples.
- $P(x_1, x_2, \dots, x_n | c_j)$
 - $O(|X|^n \cdot |C|)$ parameters
 - Could only be estimated if a very, very large number of training examples was available.

Naïve Bayes Conditional Independence Assumption:

Assume that the probability of observing the conjunction of attributes is equal to the product of the individual probabilities $P(x_j | c_j)$.

→ $O(|X| \cdot |C|)$ parameters

The Naïve Bayes Classifier

- **Conditional Independence Assumption:** features detect term **presence** and are independent of each other given the class:

$$P(X_1, \dots, X_5 | C) = P(X_1 | C) \cdot P(X_2 | C) \cdot \dots \cdot P(X_5 | C)$$

- This model is appropriate for binary variables
 - **Multivariate binomial model**

Learning the Model

- First attempt: maximum likelihood estimates
 - simply use the frequencies in the data

$$\hat{P}(c_j) = \frac{N(C = c_j)}{N}$$

$$\hat{P}(x_i | c_j) = \frac{N(X_i = x_i, C = c_j)}{N(C = c_j)}$$

NB Bernoulli: the Learning stage

```
TRAINBERNOULLINB( $\mathbf{C}, \mathbf{ID}$ )
1   $V \leftarrow \text{EXTRACTVOCABULARY}(\mathbf{ID})$ 
2   $N \leftarrow \text{COUNTDOCS}(\mathbf{ID})$ 
3  for each  $c \in \mathbf{C}$ 
4  do  $N_c \leftarrow \text{COUNTDOCSINCLASS}(\mathbf{ID}, c)$ 
5      $\text{prior}[c] \leftarrow N_c / N$ 
6     for each  $t \in V$ 
7     do  $N_{ct} \leftarrow \text{COUNTDOCSINCLASSCONTAININGTERM}(\mathbf{ID}, c, t)$ 
8          $\text{condprob}[t][c] \leftarrow (N_{ct} + 1) / (N_c + 2)$ 
9  return  $V, \text{prior}, \text{condprob}$ 
```

Problems to be solved to apply Bayes

- Determine the notion of document as the joint event
 $D=(x_1, x_2, \dots, x_n)=(x_{D1}, x_{D2}, \dots, x_{Dn})$

- Determine how x_i is related to the document content

- ➔ • Determine how to estimate

- $P(C_j)$ for the different classes $j=1, \dots, k$
- $P(x^D_i)$ for the different properties/features $i=1, \dots, n$
- $P(x^D_1, x^D_2, \dots, x^D_n | C_j)$ for the different tuples and classes

- Define the law that select among the different

$$P(C_j | x^D_1, x^D_2, \dots, x^D_n) \quad j=1, \dots, k$$

- Argmax? Best m scores? Thresholds?

Problems to be solved to apply Bayes

- 
- Define the law that selects among the different

$$P(C_j | x^D_1, x^D_2, \dots, x^D_n) \quad j=1, \dots, k$$

- (A) Argmax? (B) Best m scores? (C) Thresholds?
- A. **ARGMAX** is applicable for every task in which *multiclassification is not applicable*:
- Spam/not spam
 - FAKE news detection
- B. When a fixed number ($n > 1$) of categories is requested seemingly the model output the **n most likely classes**
- C. **Thresholds** are usually *estimated from the training data*

NB Bernoulli Model: Classification

- When multiclassification is not necessary:

```
APPLYBERNOULLINB( $\mathbf{C}, V, \text{prior}, \text{condprob}, d$ )
1   $V_d \leftarrow \text{EXTRACTTERMSFROMDOC}(V, d)$ 
2  for each  $c \in \mathbf{C}$ 
3  do  $\text{score}[c] \leftarrow \log \text{prior}[c]$ 
4     for each  $t \in V$ 
5     do if  $t \in V_d$ 
6         then  $\text{score}[c] += \log \text{condprob}[t][c]$ 
7         else  $\text{score}[c] += \log(1 - \text{condprob}[t][c])$ 
8  return  $\arg \max_{c \in \mathbf{C}} \text{score}[c]$ 
```

Problem with Max Likelihood

$$P(X_1, \dots, X_5 | C) = P(X_1 | C) \cdot P(X_2 | C) \cdot \dots \cdot P(X_5 | C)$$

- What if we have seen no training cases where patient had *no flu* and *muscle aches*?

$$\hat{P}(X_5 = t | C = nf) = \frac{N(X_5 = t, C = nf)}{N(C = nf)} = 0$$

- Zero probabilities cannot be conditioned away, no matter the other evidence!

$$\ell = \arg \max_c \hat{P}(c) \prod_i \hat{P}(x_i | c)$$

Smoothing

- *Laplace smoothing*
 - every feature has an a priori probability p ,
 - It is assumed that it has been observed in a number of m virtual examples.

$$P(x_j | c_i) = \frac{n_{ij} + mp}{n_i + m}$$

- Usually
 - A uniform distribution on all words is assumed so that $p = 1/|V|$ and $m = |V|$
 - It is equivalent to observing every word in the dictionary once for each category.

Smoothing to Avoid Overfitting

$$\hat{P}(x_i | c_j) = \frac{N(X_i = x_i, C = c_j) + 1}{N(C = c_j) + k}$$

of diff. values of X_i

- Somewhat more subtle version

k expresses the different data **bins**

overall fraction in data where $X_i = x_{i,k}$

$$\hat{P}(x_{i,k} | c_j) = \frac{N(X_i = x_{i,k}, C = c_j) + mp_{i,k}}{N(C = c_j) + m}$$

extent of “smoothing”,
numb. of bins

Bayesian Classification: an alternative view

- Is there any alternative way of looking to the *joint* event $C \wedge D$?
- In the **Bernoulli model**, we determine the occurrence the event D as a instantaneous selection of individual words w_j from the Vocabulary V
 - Every D is a subset of V , thus characterized by a **binary string** across the entire V
 - There are as many binary strings as $2^{|V|}$
- An alternative consists in modelling the event D as the occurrence of some words w_j in m distinct positions, where m is $|D|$, i.e. the size of the document
- This brings to map a document D into a sequence of words (w_1, \dots, w_m) from V , i.e. **strings of words**
- The resulting model is called **Multinomial model** as every positions corresponds to a different stochastic variable

A digression: Stochastic Language Models

- Models *probability* of generating strings in the language (commonly all strings over an alphabet Σ), e.g., **unigram** model

Model M

0.2	the					
		the	man	likes	the	woman
0.1	a	—	—	—	—	—
0.01	man	0.2	0.01	0.02	0.2	0.01
0.01	woman					
0.03	said					
0.02	likes					
...						

multiply

$P(s | M) = 0.00000008$

Stochastic Language Models

- Model *probability* of generating any string

Model M1	
0.2	the
0.01	class
0.0001	sayst
0.0001	pleaseth
0.0001	yon
0.0005	maiden
0.01	woman

Model M2	
0.2	the
0.0001	class
0.03	sayst
0.02	pleaseth
0.1	yon
0.01	maiden
0.0001	woman

the	class	pleaseth	yon	maiden
0.2	0.01	0.0001	0.0001	0.0005
0.2	0.0001	0.02	0.1	0.01

$$P(s|M2) > P(s|M1)$$

Unigram and higher-order models

$$P(\bullet \color{red}\bullet \color{yellow}\bullet \color{blue}\bullet)$$

$$= P(\bullet)P(\color{yellow}\bullet | \color{red}\bullet) P(\color{red}\bullet | \color{red}\bullet \color{yellow}\bullet)P(\color{blue}\bullet | \color{red}\bullet \color{yellow}\bullet \color{red}\bullet)$$

- Unigram Language Models

$$P(\bullet) P(\color{yellow}\bullet) P(\color{red}\bullet) P(\color{blue}\bullet)$$

Easy.
Effective!

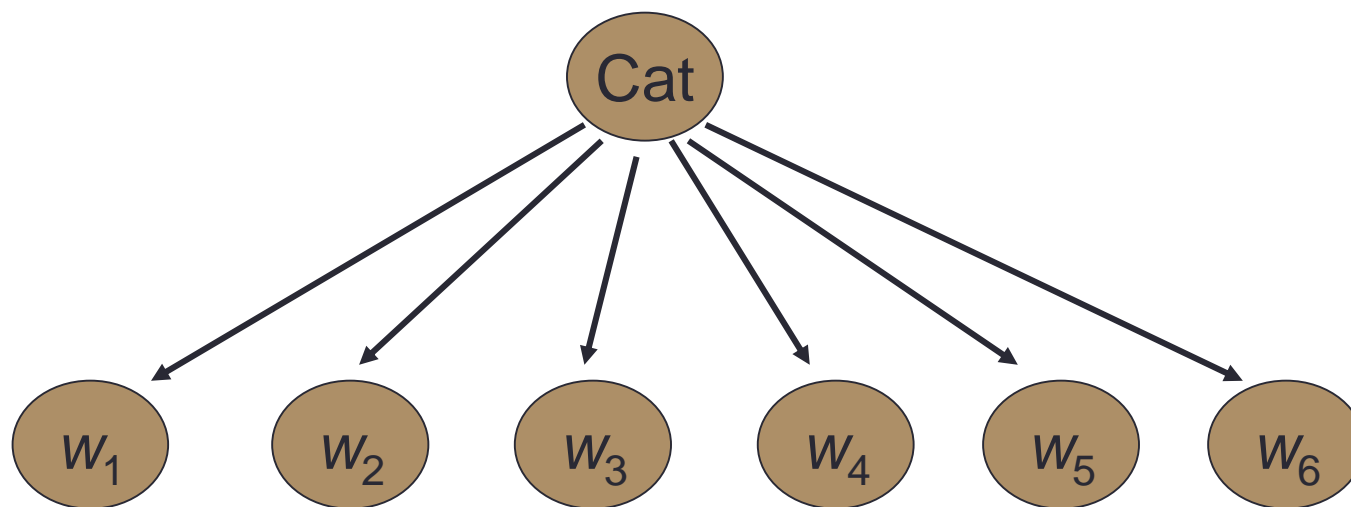

- Bigram (generally, n-gram) Language Models

$$P(\bullet) P(\color{yellow}\bullet | \color{red}\bullet) P(\color{red}\bullet | \color{yellow}\bullet) P(\color{blue}\bullet | \color{red}\bullet)$$

- Other **Language Models**

- Grammar-based models (such as Probabilistic Context Free Grammars, PCFG), etc.
 - Probably not the first thing to try in IR

Naïve Bayes via a class conditional language model = multinomial NB

- Effectively, the probability of each class is done as a class-specific unigram language model

Using Multinomial Naive Bayes Classifiers to Classify Text: Basic method

- Attributes are text positions, values are words.

$$\begin{aligned}c_{NB} &= \operatorname{argmax}_{c_j \in C} P(c_j) \prod_i P(x_i | c_j) \\ &= \operatorname{argmax}_{c_j \in C} P(c_j) P(x_1 = \text{"our"} | c_j) \dots P(x_n = \text{"text"} | c_j)\end{aligned}$$

- Still too many possibilities
- Assume that classification is *independent* of the positions of the words
 - Use same parameters for each position
 - Result is bag of words model (over tokens not types)

Multinomial Naïve Bayes: Learning

- From training corpus, extract *Vocabulary*
- Calculate required $P(c_j)$ and $P(x_k / c_j)$ terms
 - For each c_j in C do
 - $docs_j \leftarrow$ subset of documents for which the target class is c_j

- $$P(c_j) \leftarrow \frac{|docs_j|}{|\text{total \# documents}|}$$

- $Text_j \leftarrow$ single document containing all $docs_j$
- for each word x_k in *Vocabulary*
 - $n_k \leftarrow$ number of occurrences of x_k in $Text_j$
 - $$P(x_k | c_j) \leftarrow \frac{n_k + \alpha}{n + \alpha |Vocabulary|}$$

Multinomial Naïve Bayes: Classifying

- positions ← all word positions in current document which contain tokens found in *Vocabulary*
- Return c_{NB} , where

$$c_{NB} = \operatorname{argmax}_{c_j \in \mathcal{C}} P(c_j) \prod_{i \in \text{positions}} P(x_i | c_j)$$

Naive Bayes: Time Complexity

- **Training Time:** $O(|D|L_d + |C|V)$

where L_d is the average length of a document in D .

- Assumes V and all D_i , n_i , and n_{ij} pre-computed in $O(|D|L_d)$ time during one pass through all of the data.
- Generally just $O(|D|L_d)$ since usually $|C|V < |D|L_d$

- **Test Time:** $O(|C|L_t)$

where L_t is the average length of a test document.

- Very efficient overall, linearly proportional to the time needed to just read in all the data.

Multinomial NB: Learning Algorithm

```

TRAINMULTINOMIALNB( $\mathbb{C}, \mathbb{ID}$ )
1   $V \leftarrow \text{EXTRACTVOCABULARY}(\mathbb{ID})$ 
2   $N \leftarrow \text{COUNTDOCS}(\mathbb{ID})$ 
3  for each  $c \in \mathbb{C}$ 
4  do  $N_c \leftarrow \text{COUNTDOCSINCLASS}(\mathbb{ID}, c)$ 
5      $\text{prior}[c] \leftarrow N_c / N$ 
6      $\text{text}_c \leftarrow \text{CONCATENATETEXTOFALLDOCSINCLASS}(\mathbb{ID}, c)$ 
7     for each  $t \in V$ 
8     do  $T_{ct} \leftarrow \text{COUNTTOKENSOFTERM}(\text{text}_c, t)$ 
9     for each  $t \in V$ 
10    do  $\text{condprob}[t][c] \leftarrow \frac{T_{ct} + 1}{\sum_{t'} (T_{ct'} + 1)}$ 
11  return  $V, \text{prior}, \text{condprob}$ 

```

Multinomial NB: Classification Algorithm

```
APPLYMULTINOMIALNB( $\mathbf{C}, V, \text{prior}, \text{condprob}, d$ )  
1  $W \leftarrow \text{EXTRACTTOKENSFROMDOC}(V, d)$   
2 for each  $c \in \mathbf{C}$   
3 do  $\text{score}[c] \leftarrow \log \text{prior}[c]$   
4   for each  $t \in W$   
5     do  $\text{score}[c] += \log \text{condprob}[t][c]$   
6 return  $\arg \max_{c \in \mathbf{C}} \text{score}[c]$ 
```

Underflow Prevention

- Multiplying lots of probabilities, which are between 0 and 1 by definition, can result in floating-point underflow.
- Since $\log(xy) = \log(x) + \log(y)$, it is better to perform all computations by summing logs of probabilities rather than multiplying probabilities.
- Class with highest final un-normalized log probability score is still the most probable.

$$c_{NB} = \operatorname{argmax}_{c_j \in C} \log P(c_j) + \sum_{i \in \text{positions}} \log P(x_i | c_j)$$

Note on the two models

- Model 1: Multivariate binomial
 - One feature X_w for each word in dictionary
 - $X_w = \text{true}$ in document d if w appears in d
 - Naive Bayes assumption:
 - Given the document's topic, appearance of one word in the document tells us nothing about chances that another word appears
- This is the model used in the binary independence model in classic probabilistic relevance feedback in hand-classified data (Maron in IR was a very early user of NB)

Note: the two models (2)

- Model 2: Multinomial = Class conditional unigram
 - One feature X_i for each word pos in document
 - feature's values are all words in dictionary
 - Value of X_i is the word in position i
 - Naïve Bayes assumption:
 - Given the document's topic, word in one position in the document tells us nothing about words in other positions
 - Second assumption:
 - Word appearance does not depend on position

$$P(X_i = w | c) = P(X_j = w | c)$$

for all positions i, j , word w , and class c

- Just have one multinomial feature predicting all words

Parameter estimation

- Binomial model:

$$\hat{P}(X_w = \textit{true} \mid c_j) = \text{fraction of documents of topic } c_j \text{ in which word } w \text{ appears}$$

- Multinomial model:

$$\hat{P}(X_i = w \mid c_j) = \text{fraction of times in which word } w \text{ appears across all documents of topic } c_j$$

- Can create a mega-document for topic j by concatenating all documents in this topic
- Use frequency of w in mega-document

Classification

- Multinomial vs Multivariate binomial?
 - Multinomial is in general better
 - See results figures later

NB example

- Given: 4 documents
 - D1 (SPORTS): China soccer
 - D2 (SPORTS): Japan baseball
 - D3 (POLITICS): China trade
 - D4 (POLITICS): Japan Japan exports
- Classify:
 - D5: soccer
 - D6: Japan
- Use
 - Add-one smoothing
 - Multinomial model
 - Multivariate binomial model

NB example

- $p(\text{SPORTS})=0.5$
- $p(\text{POLITICS})=0.5$
- $V = \{\text{China, soccer, baseball, Japan, trade, exports}\}$

Multivariate Binomial

$$p(\text{China}|\text{SPORTS})=1/2 \text{ (o meglio } (1+1)/(2+2))$$

$$p(\text{soccer}|\text{SPORTS})=(1+1)/(2+2)$$

...

$$p(\text{exports}|\text{SPORTS})=(0+1)/(2+2)$$

$$p(\text{China}|\text{POLITICS})=(1+1)/(2+2)$$

$$p(\text{soccer}|\text{POLITICS})=(0+1)/(2+2)$$

...

$$p(\text{exports}|\text{POLITICS})=(1+1)/(2+2)$$

$$p(\text{SPORTS}|D5) \text{ ca} =$$

$$p(D5|\text{SPORTS})p(\text{SPORTS}) =$$

$$(1-p(\text{China}|\text{SPORTS}))p(\text{soccer}|\text{SPORTS}) \dots (1-p(\text{exports}|\text{SPORTS}))= \\ 1/2 * 1/2 * \dots * (1-1/4) * (0.5)$$

$$p(\text{POLITICS}|D5) \text{ ca} =$$

$$p(D5|\text{POLITICS})p(\text{POLITICS}) =$$

$$(1-p(\text{China}|\text{POLITICS}))p(\text{soccer}|\text{POLITICS}) \dots (1-p(\text{exports}|\text{POLITICS}))= \\ 1/2 * 1/4 * \dots * (1-1/2) * (0.5)$$

da cui $p(\text{POLITICS}|D5) < p(\text{SPORTS}|D5)$, e quindi:

$D5 \text{ SPORTS AND } D5 \text{ POLITICS}$

Multinomial NB

Again:

$$V = \{\text{China, soccer, baseball, Japan, trade, exports}\}$$

$$p(\text{SPORTS})=0.5$$

$$p(\text{POLITICS})=0.5$$

$$p(\text{China}|\text{SPORTS})=(1+1)/(4+2)$$

$$p(\text{soccer}|\text{SPORTS})=(1+1)/(4+2)$$

...

$$p(\text{exports}|\text{SPORTS})=(0+1)/(4+2)$$

$$p(\text{China}|\text{POLITICS})=(1+1)/(5+2)$$

$$p(\text{soccer}|\text{POLITICS})=(0+1)/(5+2)$$

...

$$p(\text{exports}|\text{POLITICS})=(1+1)/(5+2)$$

$$p(\text{SPORTS}|D5) = \text{ca}$$

$$= p(D5|\text{SPORTS})p(\text{SPORTS})=p(\text{soccer}|\text{SPORTS})p(\text{SPORTS})=1/6$$

$$p(\text{POLITICS}|D5) = \text{ca}$$

$$p(D5|\text{POLITICS})p(\text{POLITICS})=p(\text{soccer}|\text{POLITICS})p(\text{POLITICS})= \\ = (1/7) * (1/2) = 1/14$$

da cui $p(\text{POLITICS}|D5) < p(\text{SPORTS}|D5)$, e quindi:

$D5 \in \text{SPORTS AND } D5 \notin \text{POLITICS}$

Feature Selection: Why?

- Text collections have a large number of features
 - 10,000 – 1,000,000 unique words ... and more
- Feature Selection:
 - **is the process by which a large set of available features are neglected during the classification**
 - Not reliable, not well estimated, not useful
- May make using a particular classifier feasible, e.g. reduce the training time
 - Some classifiers can't deal with 100,000 of features
 - Training time for some methods is quadratic or worse in the number of features
- Can improve generalization (performance)
 - Eliminates noise features+ Avoids overfitting

Feature selection: how?

- Two idea:
 - Hypothesis testing statistics:
 - Are we confident that the value of one categorical variable is associated with the value of another
 - Chi-square test
 - Information theory:
 - How much information does the value of one categorical variable give you about the value of another
 - Mutual information
- They're similar, but χ^2 measures confidence in association, (based on available statistics), while MI measures extent of association (assuming perfect knowledge of probabilities)

Feature selection via Mutual Information

- In training set, choose k words which best discriminate (give most info on) the categories.
- The Mutual Information between a word w and a class c is:

$$I(w, c) = \sum_{e_w \in \{0,1\}} \sum_{e_c \in \{0,1\}} p(e_w, e_c) \log \frac{p(e_w, e_c)}{p(e_w)p(e_c)}$$

- For each word w and each category c

Feature selection via Mutual Information

- In training set, choose k words which best discriminate (give most info on) the categories.
- The Mutual Information between a word w and a class c is:

$$I(W = w, C = c) = \sum_{\substack{W=w \\ W \neq w}} \sum_{\substack{C=c \\ C \neq c}} p(W, C) \log \frac{p(W, C)}{p(W)p(C)}$$

- For each word w and each category c

Feature selection via MI (contd.)

- For each category we build a list of k most discriminating terms.
- For example (on 20 Newsgroups):
 - ***sci.electronics***: circuit, voltage, amp, ground, copy, battery, electronics, cooling, ...
 - ***rec.autos***: car, cars, engine, ford, dealer, mustang, oil, collision, autos, tires, toyota, ...
- Greedy: does not account for correlations between terms
- Why?

Feature Selection

- Mutual Information
 - Clear information-theoretic interpretation
 - May select rare uninformative terms
- Chi-square
 - Statistical foundation
 - May select very slightly informative frequent terms that are not very useful for classification
- Just use the commonest terms?
 - No particular foundation
 - In practice, this is often 90% as good

Feature selection for NB

- In general feature selection is *necessary* for binomial NB.
- Otherwise you suffer from noise, multi-counting
- “Feature selection” really means something different for multinomial NB. It means dictionary truncation
 - **The multinomial NB model only has 1 feature**
- This “feature selection” normally isn’t needed for multinomial NB, but may help a fraction with quantities that are badly estimated

Evaluating Categorization

- Evaluation must be done on test data that are independent of the training data (usually a disjoint set of instances).
- **Classification accuracy**: c/n where n is the total number of test instances and c is the number of test instances correctly classified by the system.
- Results can vary based on sampling error due to different training and test sets.
- Average results over multiple training and test sets (splits of the overall data) for the best results.

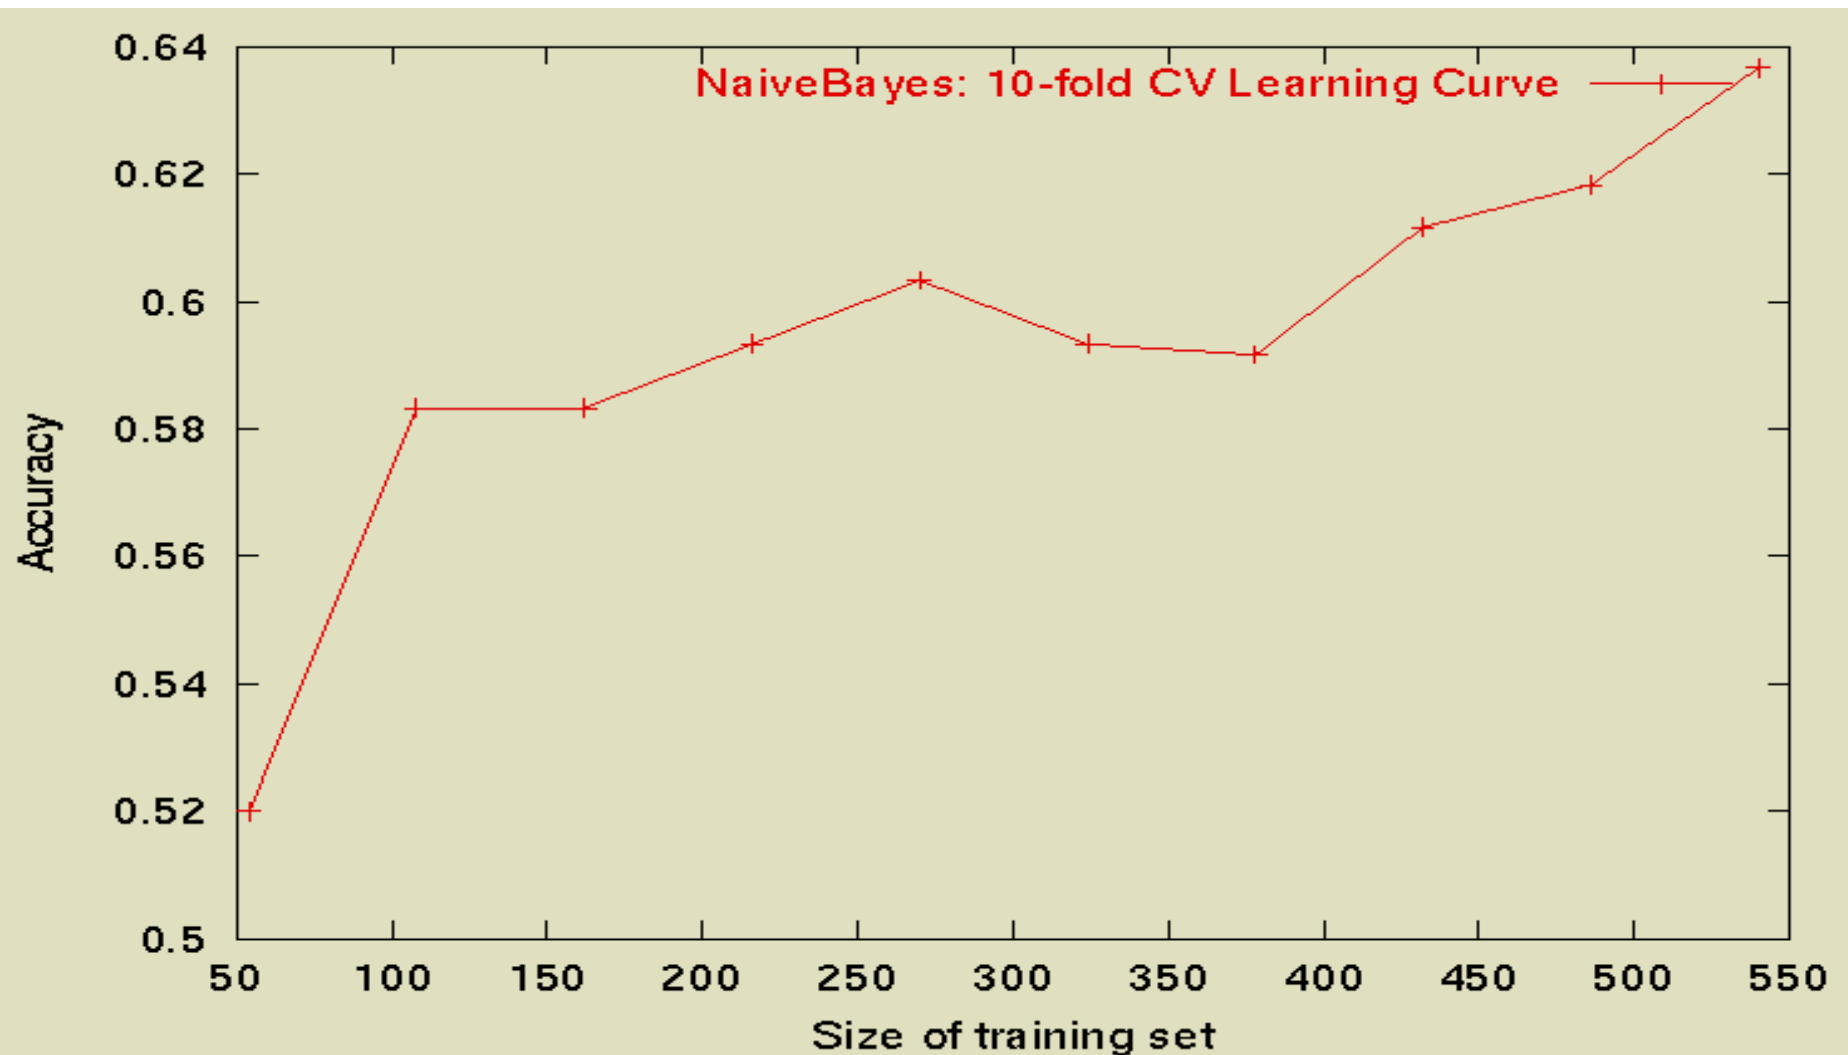

Example: AutoYahoo!

- Classify 13,589 Yahoo! webpages in “Science” subtree into 95 different topics (hierarchy depth 2)

Sample Learning Curve

(Yahoo Science Data): need more!

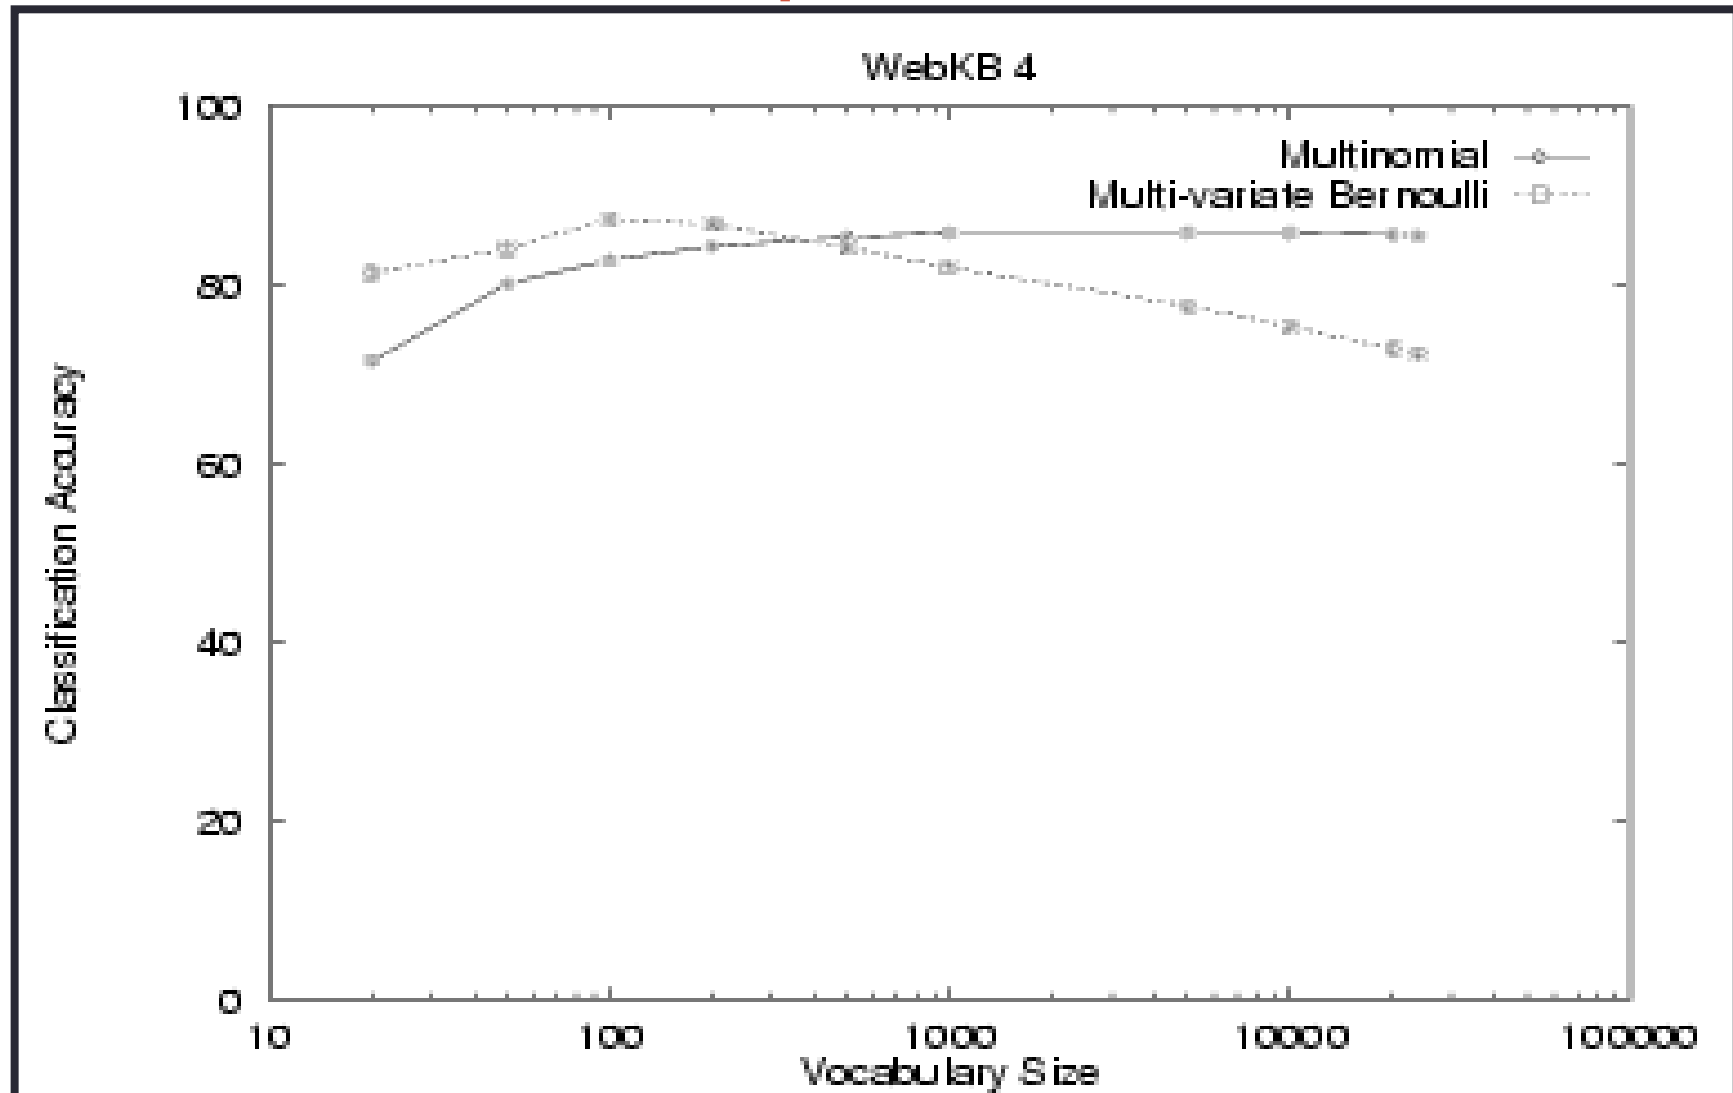

WebKB Experiment

- Classify webpages from CS departments into:
 - student, faculty, course, project
- Train on ~5,000 hand-labeled web pages
 - Cornell, Washington, U.Texas, Wisconsin
- Crawl and classify a new site (CMU)
- Results:

	Student	Faculty	Person	Project	Course	Department
Extracted	180	66	246	99	28	1
Correct	130	28	194	72	25	1
Accuracy:	72%	42%	79%	73%	89%	100%

Naïve Bayes on spam email

Violation of NB Assumptions

- Conditional independence
- “Positional independence”
- Examples?
 - *Computer vs. science* in the **Technology** category
 - *par vs. conditio* in the **Law, Politics** category
 - *Box office vs. Office Box*
 - *Taxonomy tree vs. Tree taxonomy*
 - *(Dog eats vs. eating dogs) vs. (Eating vegetables vs. vegetables eat)*

Naïve Bayes Posterior Probabilities

- Classification results of naïve Bayes (the class with maximum posterior probability) are usually fairly accurate.
- However, due to the inadequacy of the conditional independence assumption, the actual posterior-probability numerical estimates are not.
 - Output probabilities are generally very close to 0 or 1.

When does Naive Bayes work?

- Sometimes NB performs well even if the Conditional Independence assumptions are **badly** violated.
- Classification is about predicting the correct class label and NOT about accurately estimating probabilities.

Assume two classes c_1 and c_2 .

A new case A arrives.

NB will classify A to c_1 if:

$$P(A, c_1) > P(A, c_2)$$

	$P(A, c_1)$	$P(A, c_2)$	Class of A
Actual Probability	0.1	0.01	c_1
Estimated Probability by NB	0.08	0.07	c_1

Besides the big error in estimating the probabilities the classification is still **correct**.

Correct estimation \Rightarrow accurate prediction

but **NOT**

accurate prediction  Correct estimation

Naive Bayes is *not-so*-Naive

- **Naïve Bayes: First and Second place in KDD-CUP 97 competition, among 16 (then) state of the art algorithms**
 - Goal: Financial services industry direct mail response prediction model: Predict if the recipient of mail will actually respond to the advertisement – 750,000 records.
- **Robust to Irrelevant Features**
 - Irrelevant Features cancel each other without affecting results
 - Instead Decision Trees can **heavily** suffer from this.
- **Very good in domains with many equally important features**
 - Decision Trees suffer from *fragmentation* in such cases – especially if little data
- **A good dependable baseline for text classification (but not the best)!**
- **Optimal if the Independence Assumptions hold:** If assumed independence is correct, then it is the Bayes Optimal Classifier for problem
- **Very Fast:** Learning with one pass over the data; testing linear in the number of attributes, and document collection size
- **Low Storage requirements**

Summary

- A general type of learning is the probabilistic one. Learning here means
 - Describe the problem through a **generative model** that makes the relations between input (e.g. symptoms) and output variables (e.g. diagnoses) explicit
 - Find the **best parameters for the model** (i.e. analytical probability distributions or estimation of discrete probabilities) able to decide about the problem in an accurate way
- An example: NB document classification (discrete case)
- Most applied models:
 - **Multivariate Binomial** (o **Bernoulli**) NB
 - **Multinomial NB**

Summary (2)

- In estimating the parameters of a NB classifiers a central role is played by the so-called *smoothing* techniques: inaccurate estimation processes may result in a poor, i.e. inaccurate, results
 - Smoothing allows to improve the estimate of some parameters that are particularly problematic
 - Some target phenomena (e.g. very rare words)
 - Structural lacks on the adopted annotated sample
- NB classification is to be preferred for its robustness and efficiency
- It is widely adopted as a baseline in several researches and applications
